Pozzolanic aggregates

Lancaster 2019

(a) Amorphous

(b) Crystalline

Pozzolanic aggregates are materials with an amorphous structure, rich in silica and alumina, and potentially reactive with a lime binder through the medium of a liquid (water) under slightly alkaline conditions (basic pH)

Volcanic pozzolans

Volcanic pozzolans consist of volcanic rocks having a quasi-eminently pyroclastic origin (produced by explosive volcanic activities) and having high concentrations of silica and active alumina in amorphous or poorly crystalline rocks

Therefore they are potentially reactive with lime in mortars: they encompass many pyroclastic products with abundant volcanic glass, such as pumice, volcanic ash, tephra, perlites and obsidians, poorly lithified tuffs and ignimbrites, and breccias

Volcanic pozzolans

Pumice

Highly vesicular rough-textured volcanic glass

Scoria

Vesicular, dark-colored volcanic rock usually feebly-to-moderately silica undersaturated.

Tuffs

Volcanic ashes, scoria, pumices and other volcanic products lithified after sedimentation into a rock

Un lithified pumice outcrop (Phlegraean Fields, Naples)

Lithified tuff outcrop (Phlegraean Fields, Naples)

Volcanic pozzolans

Obsidian and perlites

Obsidian is a natural glass formed by the rapid cooling of extremely silica-rich magmas (about 65 to 80%), having a very low in water content.

Perlite is an amorphous volcanic glass, very rich in SiO_2 , having a high-water content, typically formed by the hydration of obsidian.

Perlite outcrop embedding obsidians
(Monte Arci, Sardinia)

Harenae fossiciae

In caementiciis autem structuris primum est de harena quaerendum, ut ea sit idonea ad materiem miscendam neque habeat terram commixtam. genera autem harenae fossiciae sunt haec, nigra, cana, rubra, carbunculus.

In buildings of rubble work it is of the first importance that the sand be fit for mixing with the lime, and unalloyed with earth. The different sorts are these; black, white, deep red, and bright red.

Vitr. *De arch.* 2.5.1

recentes autem fossiciae cum in structuris tantas habeant virtutes, eae in tectorio ideo non sunt utiles quod pinguitudine eius calx palea commixta propter vehementiam non potest sine rimis inarescere.

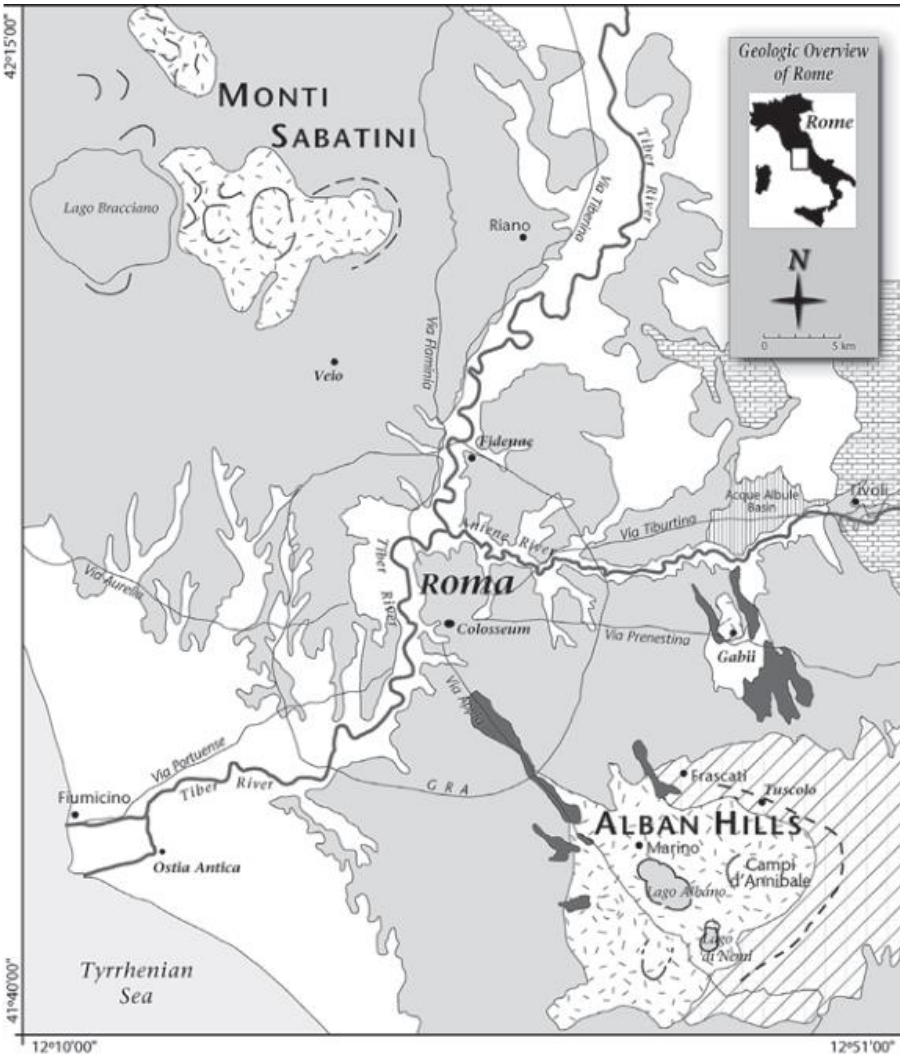

Though pit sand (*harenae fossiciae*) is excellent for mortar, it is unfit for plastering; for being of such a rich quality, when added to the lime and straw, its great strength does not suffer it to dry without cracks.

Vitr. *De arch.* 2.5.3

Pulvis puteolana

Vitruvio, De arch., V, 12, 2-3.

Eae autem structurae, quae in aqua sunt futurae, videntur sic esse faciendae, uti portetur pulvis a regionibus quae sunt a Cumis continuatae ad promontorium Minervae [...]. Deinde tunc in eo loco, qui definitus erit, arcae stipitibus robusteis et catenis inclusae in aquam demittendae destinandaeque firmiter: deinde inter eas ex transtillis inferior pars sub aqua exequenda et purganda, et caementis ex mortario materia mixta (quemadmodum supra scriptum est) ibi congerendum, donicum compleatur structurae spatium, quod fuerit inter arcae.

The structures to be made in the water, it seems to me, should be done in this manner. Let the dust be transported from those regions which extend from Cumae to the promontory of Minerva [...]. In the place that will be established, let the closed arches be dropped into the water and connected validly with strong poles and chains: moreover inside those by means of rafts purge and level the lower part under the water, and then throw in cement matter mixed with lime (as was said above), until that space of structure that there is between the arches is filled.

Geochemistry of volcanic rocks

- **Geochemistry** is the science that uses the tools and principles of chemistry to explain the mechanisms behind major geological systems such as the Earth's crust and its oceans.
- In geology, **igneous differentiation, or magmatic differentiation**, is an umbrella term for the various processes by which magmas undergo bulk chemical change during the partial melting process, cooling, emplacement, or eruption. The sequence of magmas produced by igneous differentiation is known as a **magma series**.
- In magmatic differentiation differences in chemical composition are affected by several factors (i.e. Distinct melting events from distinct sources; Crystal fractionation; Mixing of 2 or more magmas; Assimilation/contamination of magmas by crustal rocks
- This results in variation in the concentration of chemical **major elements** (in particular Si), and in the **trace element** concentrations. Trace elements are elements that occur in low concentrations in rocks, usually less than 0.1 % (usually reported in units of parts per million, ppm).

Geochemistry of volcanic rocks

When considering the rocks in the mantle, trace elements can be divided into ***incompatible elements***, those that do not easily fit into the crystal structure of minerals in the mantle, and ***compatible elements***, those that do fit easily into the crystal structure of minerals in the mantle.

- Incompatible elements - these are elements like K, Rb, Cs, Ta, Nb, U, Th, Y, Hf, Zr, and the ***Rare Earth Elements*** (REE)- La, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, & Lu. Most have a large ionic radius. Mantle minerals like olivine, pyroxene, spinel, & garnet do not have crystallographic sites for large ions.
- Compatible elements - these are elements like Ni, Cr, Co, V, and Sc, which have smaller ionic radii and fit more easily into crystallographic sites that normally accommodate Mg, and Fe.

When a mantle rock begins to melt, the incompatible elements will be ejected preferentially from the solid and enter the liquid. This is because if these elements are present in minerals in the rock, they will not be in energetically favorable sites in the crystals. As melting proceeds the concentration of these incompatible elements will decrease because (1) there will be less of them to enter the melt, and (2) their concentrations will become more and more diluted as other elements enter the melt.

Geochemistry of volcanic rocks

Abundance of the elements in various average volcanic rocks is shown as weight percent (wt.%=g per 100 g of rock) of the oxide for SiO₂, TiO₂, Al₂O₃, FeO, MnO, MgO, CaO, Na₂O, K₂O, P₂O₅ or as parts per million (ppm=micrograms per g) for all other elements.

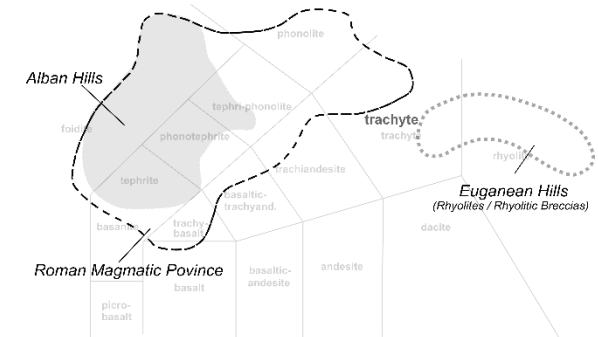

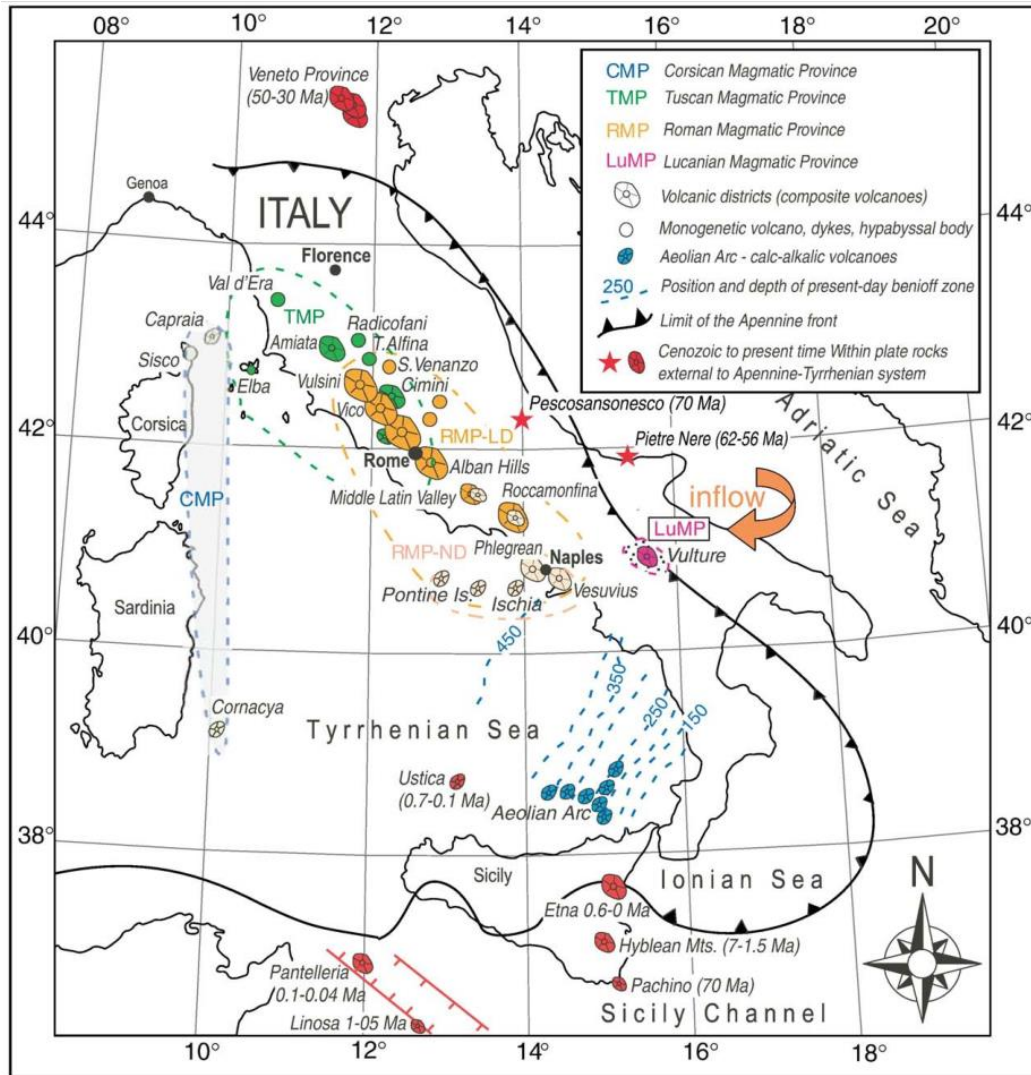

Geochemistry of volcanic rocks

TAS - Total Alkalis vs. Silica Variation Diagram. The TAS Diagram for volcanic rocks is used to classify igneous rocks using whole rock chemical data as adopted by the International Union of Geological Sciences (IUGS).

The variation diagram scatter plot of weight percent $\text{Na}_2\text{O} + \text{K}_2\text{O}$ vs. weight percent SiO_2 is divided into regions based on the whole rock chemistry of rocks with petrographically defined names (see the QAPF diagram). The TAS diagram enables classification of glassy (i.e. volcanic pozzolans) and other volcanic rocks without, or in support to, petrographic data.

Geochemistry of volcanic rocks

The analysis of discriminant trace elements (or sometimes of ratio among discriminant trace elements) can help in the discrimination of volcanic domains. i.e. in this case, to distinguish Latian from Campania magmatic districts, based on the concentrations of Nb(Niobium)/Y(Yttrium) vs Zr(Zirconium)/Y(Yttrium)

Analytical techniques

Discriminant diagrams can report multiple traces (or ratios among traces) useful for discrimination, in this case a further discriminant diagram for distinguishing Campanian Volcanoes from Latial ones is the Nb (Niobium)/Zr(Zirconium) vs Th (Thorium)/Ta(Tantalum) scatterplot

Geochemistry of volcanic rocks

Based on around 950 geochemical fingerprint of pyroclastic rocks from magmatic units of the Gulf of Naples → in-detail intra-regional provenance Yb (Ytterbium) vs Th (Thorium) scatterplot

Geochemical techniques

Main techniques used to determine the geochemical profile of volcanic rocks

- **SEM-EDS** (Scanning Electron Microscopy with Energy Dispersive X-ray Spectroscopy): semi-quantitative major chemical element profiling (expeditious but not resolving for provenance determination)
- **XRF** (X-ray fluorescence): exact quantification in terms of percentages of major and trace chemical elements, useful for provenance determination but need enough sample quantity (at least 2 grams)
- **LA-ICP-MS** (laser ablation-inductively coupled plasma-mass spectrometry): extremely useful for very high precision quantification of major and trace chemical elements in volcanic rocks. It can be done punctually to map even extremely minute areals of material, even on individual minerals.

The Punic-Roman town of Nora (Sardinia)

- Established by Phoenicians in the 8th c. BC become a Punic settlement during the 5th c. BC;
- After the Roman conquest of Sardinia, in the 3rd c. AD Nora (and Sardinia) was involved in a flourishing period of renovation, with the construction of new temples, baths and an aqueduct;
- The University of Padova (DBC) has ongoing excavation activities since 1990 (urban infrastructures, necropolis, private and public buildings)

Roman Temple (3rd c. AD)

Analytical method: XRF (coarse clasts, more than 2 grams of material from each sample available for analysis)

Roman Temple (3rd c. AD)

Full compatibility with pyroclastic products of the Gulf of Naples, in particular with the late eruptions of Phlegraean Fields (post-NYT, along the coastline of the Gulf of Naples)

Aquileia (Friuli Venezia Giulia)

- Established as *colonia latina* in 181 bC
- During the Imperial age was enriched by construction of theatre, amphitheater, circus
- In 4th-c. AD was celebrated as one of the most prestigious centers in Roman world
- In 5th-c AD falled against Attila invasion
- Reconquered by Byzantium in 6th-c. AD
- Progressively abandoned since the 7th-c. AD

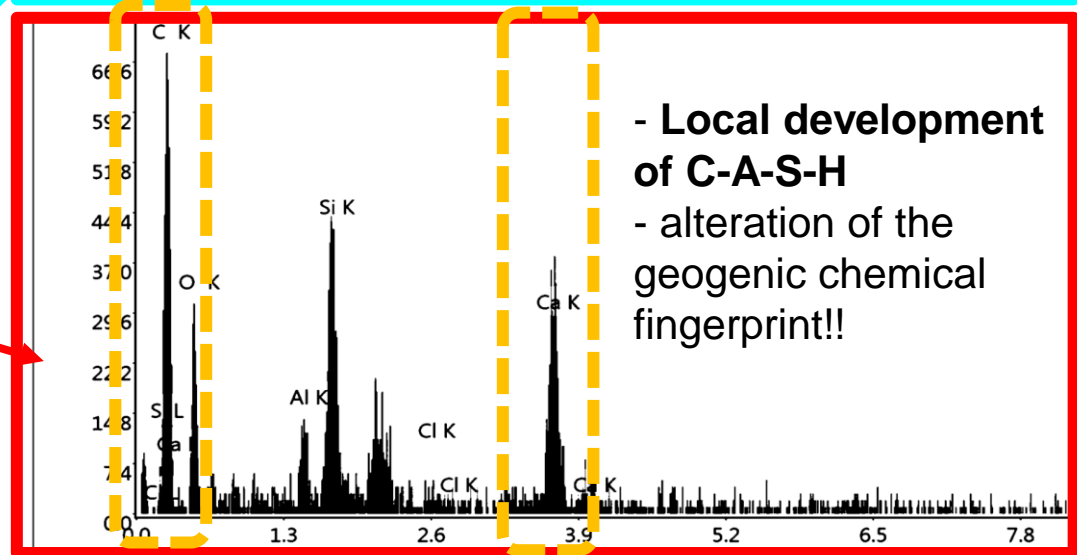

Aquileia – Theatre (beginning 1st c AD)

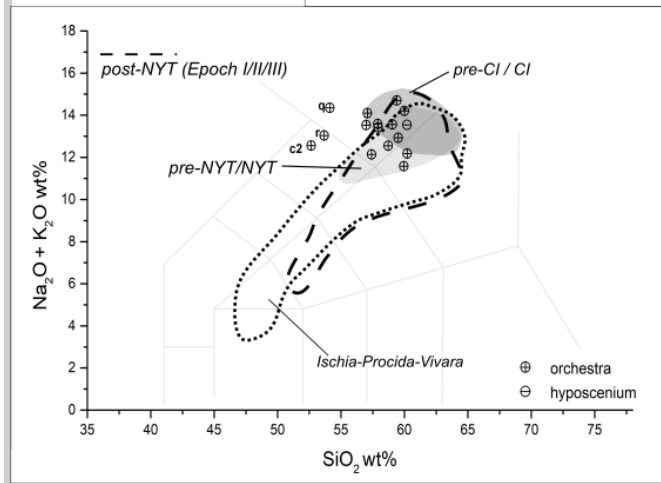

Currently under excavation by the Department of Cultural Heritage of the University of Padova

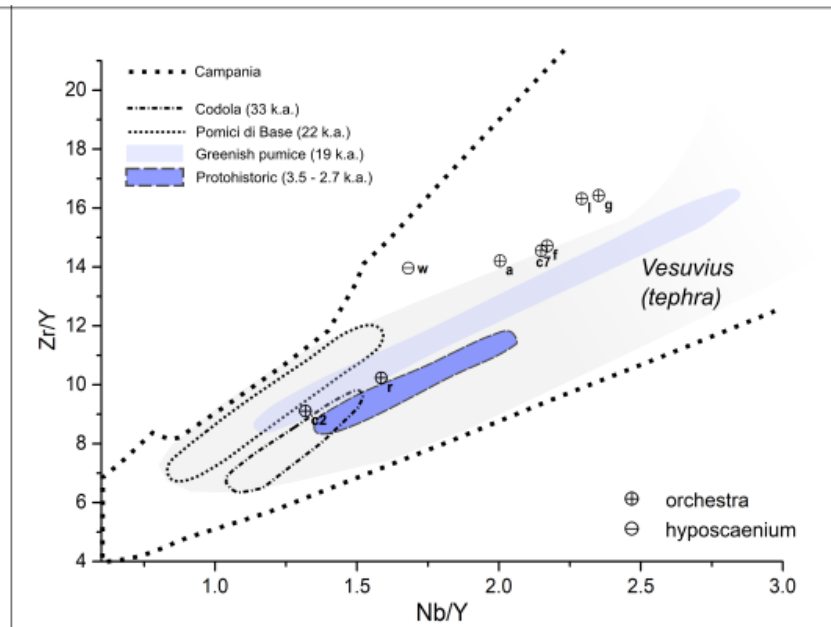

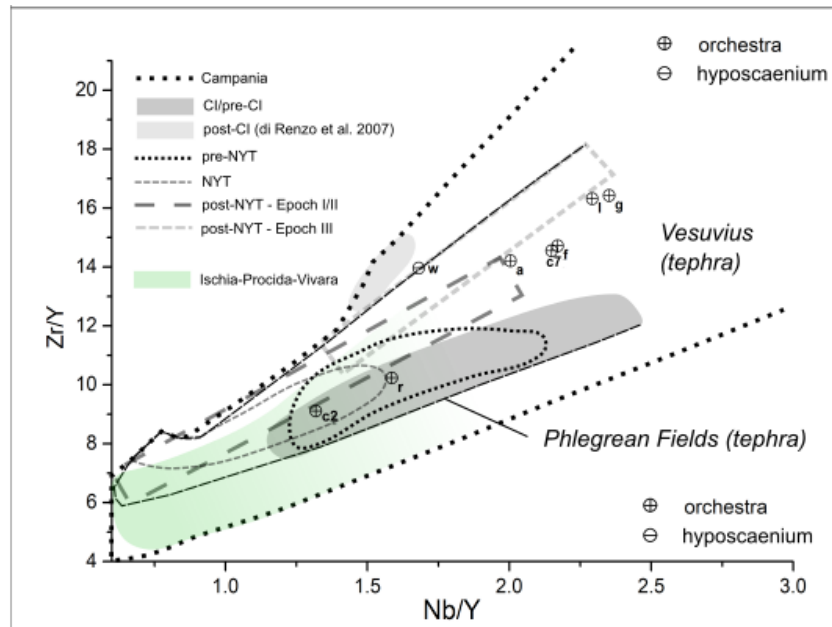

Aquileia – Theatre (beginning 1st c AD)

Aquileia – Theatre (beginning 1st c AD)

Analytical method:
SEM-EDS (major elements)

Analytical method (trace elements): LA-ICP-MS

Conclusive remarks

Conclusive remarks

- These **provenance studies** are extremely helpful in tracking the trading of materials, in this case particular building materials, in antiquity.
 - Obviously, this is only the first step: the archaeometrical analysis makes it possible to verify the provenance in many cases (or to narrow the field of possible provenances) of pozzolanic material, but from this point it is important to **contextualize the data in relation to a precise historical, historical-economic, historical-cultural framework: this is the archeological component, which must explain and motivate certain commercial choices**, with dynamics of shifting workers, technological choices required by clients
- Transition to the realm of pure archeology.
